CS 461, Lecture 7

Jared Saia
University of New Mexico

Today’s Outline

• String Alignment
• Matrix Multiplication

Alignment Review

• Create a string alignment table for the two strings “abba” and “bab”. Put “abba” at the top of the table and “bab” on the left side
• Q1: What is the alignment table for these two strings?
• Q6: What is the minimum edit distance? Give one optimal alignment.

Matrix Chain Multiplication

Problem:

• We are given a sequence of $n$ matrices, $A_1, A_2, \ldots, A_n$, where for $i = 1, 2, \ldots, n$, matrix $A_i$ has dimension $p_{i-1}$ by $p_i$
• We want to compute the product, $A_1 A_2, \ldots, A_n$ as quickly as possible.
• In particular, we want to fully parenthesize the expression above so there are no ambiguities about the how the matrices are multiplied
• A product of matrices is fully parenthesized if it is either a single matrix, or the product of two fully parenthesized matrix products, sorrounded by parantheses
There are many ways to paranthesize the matrices
Each way gives the same output (because of associativity of matrix multiplications)
However the way we paranthesize will effect the time to compute the output
Our Goal: Find a paranthesization which requires the minimal number of scalar multiplications

Example

In this example, it's much better to multiply the last two matrices first (this gives us a short, narrow matrix on the right)
Worse to multiply the first two matrices first (this gives us a short wide matrix on the left)
In general, our goal is to find ways to always create narrow and short resulting matrices.

Problem: There can be many ways to paranthesize. E.g.

- \((A_1(A_2(A_3A_4)))\)
- \((A_1((A_2A_3)A_4))\)
- \(((A_1A_2)(A_3A_4))\)
- \(((A_1(A_2A_3))A_4)\)
- \(((A_1A_2)A_3)A_4)\)

Let \(P(n)\) be the number of ways to paranthesize \(n\) matrices. Then \(P(1) = 1\)
For \(n \geq 2\), we know that a fully paranthesized product is the product of two fully paranthesized products, and the split can occur anywhere from \(k = 1\) to \(k = n - 1\).
Hence for \(n \geq 2\):

\[
P(n) = \sum_{k=1}^{n-1} P(k)P(n-k)
\]

In the hw, you will show that the solution to this recurrence is \(\Omega(2^n)\)
Q: Can we develop a DP Solution to this problem?

- **Formulate the problem recursively.** Write down a formula for the whole problem as a simple combination of answers to smaller subproblems
- **Build solutions to your recurrence from the bottom up.** Write an algorithm that starts with the base cases of your recurrence and works its way up to the final solution by considering the intermediate subproblems in the correct order.

---

**Key Observation**

- Let $A_{i..j}$ (for $i \leq j$) be the matrix that results from evaluating the product $A_iA_{i+1}...A_j$
- Imagine we are computing $A_{i..j}$
- The last multiplication we do must look like this:
  \[ A_{i..j} = (A_{i..k}) \times (A_{k+1..j}) \]
  for some $k$ between $i$ and $j - 1$
- Then total cost to compute $A_{i..j}$ is:
  - cost to compute $A_{i..k}$
  - cost to compute $A_{k+1..j}$
  - cost to multiply $A_{i..k}$ and $A_{k+1..j}$

---

**Recursive Formulation**

- For any integers $x, y$, let $m(x, y)$ be the minimum cost of computing $A_{x..y}$
- Then for any $k$ between $i$ and $j - 1$,
  \[ m(i, j) \leq \text{optimal cost to compute } A_{i..k} + \text{optimal cost to compute } A_{k+1..j} + \text{cost to multiply } A_{i..k} \text{ and } A_{k+1..j} \]
- In other words:
  \[ m(i, j) \leq m(i, k) + m(k + 1, j) + \text{cost to multiply } A_{i..k} \text{ and } A_{k+1..j} \]

---

**Cost to Multiply**

- $A_{i..k}$ is a $p_{i-1}$ by $p_k$ matrix
- $A_{k+1..j}$ is a $p_k$ by $p_j$ matrix
- Thus multiplying $A_{i..k}$ and $A_{k+1..j}$ takes $p_{i-1}p_kp_j$ operations
- Hence we have:
  \[ m(i, j) \leq m(i, k) + m(k + 1, j) + p_{i-1}p_kp_j \]
**Recursive Formulation**

- We've shown that $m(i, j) \leq m(i, k) + m(k + 1, j) + p_{i-1}p_kp_j$ for any $k = i, i + 1, \ldots, j - 1$
- Further note that the optimal parenthesization must use some value of $k = i, i + 1, \ldots, j - 1$. So we need only pick the best
- Thus we have:

  $m(i, j) = 0$ if $i = j$
  $m(i, j) = \min_{i \leq k < j} \{ m(i, k) + m(k + 1, j) + p_{i-1}p_kp_j \}$

**The Recursive Algorithm**

- We now have enough information to write a recursive function to solve the problem
- The recursive solution will have runtime given by the following recurrence:
- $T(1) = 1$,
- $T(n) = 1 + \sum_{k=1}^{n-1}(T(k) + T(n-k) + 1)$
- Unfortunately, the solution to this recurrence is $\Omega(2^n)$ (as shown on p. 346 of the text)

**DP Algorithm**

- Note that we must solve one subproblem for each choice of $i$ and $j$ satisfying $1 \leq i \leq j \leq n$
- This is only $\binom{n}{2} + n = \Theta(n^2)$ subproblems
- The recursive algorithm encounters each subproblem many times in the branches of the recursion tree.
- However, we can just compute these subproblems from the bottom up, storing the results in a table (this is the DP solution)

**Pseudocode**

```c
Matrix-Chain-Order(int p[]){
    n = p.length - 1;
    for (i=1;i<=n;i++){
        m(i,i) = 0;
    }
    for (l=2;l<=n;l++){ \l is chain length
        for (i=1;i<=n-l+1;i++){
            j = i+l-1;
            m[i,j] = MAXINT;
            for(k=i;k<=j-1;k++){
                q = m[i,k] + m[k+1,j] + p[i-1]*p[k]*p[j];
                if(q<m[i,j]){ 
                    m[i,j] = q;
                    s[i,j] = k;
                }
            }
        }
    }
}
```
Psuedocode

- This code computes both the optimal cost and a parenthesization that achieves that cost
- It uses an $m$ array to store the optimal costs of computing $m(i,j)$. It also uses a $s$ array, where $s(i,j)$ stores the $k$ value which gives $m(i,j)$
- The parenthesization can be recovered from the $s$ array using the pseudocode in the book on p. 338.

Example

- Consider the sequence of three matrices, $A_1, A_2, A_3$ whose dimensions are given by the sequence $3, 1, 2, 1$ (i.e. $p_0 = 3$, $p_1 = 1$, $p_2 = 2$, $p_3 = 1$)
- Let’s construct the tables giving the optimal parenthesization
- The $(i,j)$ entry of the first table will give the optimal cost for computing $A_{i..j}$, the $(i,j)$ entry of the second table will give a $k$ value which achieves this optimal cost

Analysis

- This code has three nested loops, each of which takes on at most $n - 1$ values, and the inner loop takes $O(1)$ time.
- Thus the runtime is $O(n^3)$
- The algorithm also requires $\Theta(n^2)$ space

Computations

- $m(1,1) = m(2,2) = m(3,3) = 0$
- $m(1,2) = p_0 p_1 p_2 = 6$
- $m(2,3) = p_1 p_2 p_3 = 2$
\[ m(1, 3) = \min \left\{ m(1, 1) + m(2, 3) + p_0p_1p_3, \right. \]
\[ \left. m(1, 2) + m(3, 3) + p_0p_2p_3 \right\} \]
\[ = \min \left\{ 0 + 2 + 3, \right. \]
\[ \left. 6 + 0 + 6 \right\} \]
\[ = 5 \]

Example, m array

\[
\begin{array}{ccc}
1 & 2 & 3 \\
1 & 0 & 6 & 5 \\
2 & - & 0 & 2 \\
3 & - & - & 0 \\
\end{array}
\]

Example, s array

\[
\begin{array}{ccc}
1 & 2 & 3 \\
1 & - & 1 & 1 \\
2 & - & - & 2 \\
3 & - & - & - \\
\end{array}
\]

Example

- Thus an optimal parenthesization is \((A_1(A_2A_3))\)
- The cost of this is 5
Consider the sequence of three matrices, \( A_1, A_2, A_3, A_4 \) whose dimensions are given by the sequence 3, 1, 2, 1, 2 (i.e. \( p_0 = 3, p_1 = 1, p_2 = 2, p_3 = 1, p_4 = 2 \)).

Let’s construct the tables giving the optimal parenthesization.

The \((i,j)\) entry of the first table will give the optimal cost for computing \( A_{i..j} \), the \((i,j)\) entry of the second table will give a \( k \) value which achieves this optimal cost.

\[
\begin{array}{cccc}
1 & 2 & 3 & 4 \\
1 & - & 1 & 1 \\
2 & - & - & 2 & 3 \\
3 & - & - & - & 3 \\
4 & - & - & - & - \\
\end{array}
\]

**Example Computation**

\[
m(1,4) = \min \left\{ \begin{array}{c}
m(1,1) + m(2,4) + p_0 p_1 p_4, \\
m(1,2) + m(3,4) + p_0 p_2 p_4, \\
m(1,3) + m(4,4) + p_0 p_3 p_4 \\
0 + 4 + 6, \\
6 + 4 + 12, \\
5 + 0 + 6 \\
\end{array} \right\}
\]

\[
m(1,4) = \min \left\{ \begin{array}{c}
10 \\
\end{array} \right\}
\]

This minimum is achieved when \( k = 1 \).
Example II

- Thus an optimal parenthesization is $(A_1((A_2A_3)A_4))$
- The cost of this is 10

In-Class Exercise

- Consider the sequence of three matrices, $A_1, A_2, A_3$ whose dimensions are given by the sequence 1, 2, 1, 2 (i.e. $p_0 = 1,\ p_1 = 2,\ p_2 = 1,\ p_3 = 2$)
- Q1: What are the m array and s array for these inputs?
- Q2: What is the optimal parenthesization?
